

Nub Theory vs. Gender Determination

16.5 weeks is when male or female sex parts are usually completely formed on most babies. Sex develops differently on each baby at varying times, just as all adults have varying genitalia so do developing babies, about 92% of all babies at 16+ weeks will give an accurate sex reading of male or female genitalia. However, a (Nub Theory) is completely different and most facilities do not explain what you are receiving when you go in for an early prediction. It is a (tubercle reading) and not a fully formed male or female sex part. These early predictions are based off the directional angle of the tubercle, which is what will develop into a male or female sex part during the morphing stage 12-16 weeks. The tubercle readings should be done between 13 – 14.5 weeks they are about 85% accurate, so approx. 85 out of 100 will be correct and approx. 15 out of 100 will be incorrect. I give parents the information to base their decision on which session they would rather schedule for? Some will come in early for a \$40.00 2D Nub Theory and then come back @ 16+ weeks to confirm before they start announcing or planning parties. I hope this information is helpful :) We do all our Gender Appointments on some Mondays and all Saturdays, remember to pick the correct package when booking online.
